

When a customer attempts a transfer of ₹50,000 and sees the generic error "Transaction could not be completed," the underlying cause could be one of several possibilities. Each of these scenarios would need to be investigated by the bank or payment system:

Potential Root Causes

- **Daily limit exceeded** — The customer has already reached the maximum transfer amount allowed for the day.
- **Insufficient balance** — The account does not have enough funds to cover the ₹50,000 transfer.
- **Bank server unavailable** — The bank's backend systems are down or under maintenance.
- **OTP expired** — The one-time password used for authentication timed out before completion.
- **Network timeout** — Connectivity issues caused the request to fail before reaching the server.
- **Beneficiary inactive** — The recipient account is dormant, closed, or flagged as inactive.
- **Fraud rule triggered** — The transaction was blocked by fraud detection systems due to unusual patterns.

- **Core banking unavailable** — The central banking system that processes transfers is temporarily down.
- **UPI switch unavailable** — If the transfer was via UPI, the national switch may have been unavailable.

How to Narrow Down the Issue

- Check if the customer has sufficient balance and hasn't exceeded limits.
- Verify if OTP was entered within the valid time window.
- Confirm whether the bank or UPI systems were experiencing downtime.
- Review fraud alerts or beneficiary account status.
